US patent application) Art Unit : 1615
N° 09/914,544
Filed: March 19, 2002) Examiner : OH.SIMON J

FOR : ORALLY DISPERSIBLE TABLET WITH LOW FRIABILITY AND
METHOD FOR PRODUCING SAME

DECLARATION UNDER RULE 132

To Honorable Commissioner of Patents and Trademarks
Washington, D.C.

Sir :

I, Edouard GENDROT, 24, rue de Dreux 28500 GARNAY,
France, do solemnly declare :

THAT I am a named inventor of the present patent application n° 09/914,544 and that I am fully familiar therewith ;

THAT I have read and understood the Office Action of September 14, 2004 in connection with the present patent application ;

THAT I have carefully read Liu et al. (US 6,465,009) and clearly understood said patent ;

THAT, tablets according to Liu et al. are different from tablets according to the invention since they are manufactured thanks to a process which is not a direct compression of a mixture of powders ;

THAT, the process according to Liu et al in which successive steps of hydration and drying of the mixture of constituents before the compression are carried out, leads to tablets presenting an internal microscopic structure different from the structure of the tablets according to the invention ;

THAT, the disintegration of the tablets according to Liu et al. is carried out by the fact that one component is a water soluble binding agent (PVP) which dissolves when the tablet is put in presence of water ;

THAT, tablets according to the invention comprise a disintegrant, which is not water soluble, e.g. crospovidone (cross-linked PVP), and when the tablet is in the presence of water, said disintegrant make the tablet exploded, with no solubilisation ;

THAT, consequently, Liu et al. does not describe, nor suggest tablets according to the invention.

I, the undersigned, declare further that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true, and, further, that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under section 1001, or Title 18, of the United States Code, and that such willful false statements may jeopardize the validity of the application or any patent issuing thereon.

Date: February 10 of 2005

Edouard GENDROT

1 General notes on synthesis and applications

1.1 Soluble polyvinylpyrrolidone (soluble Kollidon grades)

Modern acetylene chemistry is based on the work of Hepp at BASF. One of the many products of this work is N-vinylpyrrolidone (Fig. 1).

Fig. 1: Hepp's synthesis of N-vinylpyrrolidone ($\text{C}_6\text{H}_9\text{NO}$, Mr 111.1)

The first polymerization product of N-vinylpyrrolidone was soluble polyvinylpyrrolidone, which was patented in 1939. Fig. 2 shows one of the mechanisms of polymerization: free radical polymerization in water using hydrogen peroxide as initiator [1, 141].

Fig. 2 The reaction mechanism for the radical polymerization of N-vinylpyrrolidone in water.

The mechanism for terminating the polymerization reaction makes it possible to produce soluble polyvinylpyrrolidone of almost any molecular weight.

Apart from the method of production in water shown in Fig. 2, it is also possible to conduct the polymerization in an organic solvent, e.g. isopropanol. This technology is used today in the production of low-molecular polyvinylpyrrolidone for injection solutions.

The low and medium-molecular weight grades of soluble polyvinylpyrrolidone are spray-dried to produce the pharmaceutical grade Kolidon powders, while the high-molecular weight grades are roller-dried.

Soluble polyvinylpyrrolidone was first used during World War II as a blood-plasma substitute. Although it has excellent properties for this purpose, it has no longer been used for a number of decades. The organism does not metabolize the polymer, with the result that after parenteral administration, small quantities of high-molecular components may remain within the body. This problem does not exist with oral administration.

Today, soluble polyvinylpyrrolidone (e.g. Kolidon) is one of the most versatile and widely used pharmaceutical auxiliaries (see Chapter 2.4 "Soluble Kolidon grades").

It is also used in the production of one of the most important topical disinfectants, PVP-Iodine.

Fig. 2. Polymerization of N-vinylpyrrolidone.

ion reaction makes it possible to obtain polymers of almost any molecular weight.

As shown in Fig. 2, it is also possible to use an organic solvent, e.g. isopropanol, for the precipitation of low-molecular-weight polymers.

The insoluble polyvinylpyrrolidone is a high-molecular-weight polymer, e.g. Kollidon powder, which is roller-dried.

During World War II as a blood coagulant for this purpose, it was used. The organism does not absorb it, and it may remain within the body.

It is one of the most versatile polymers (see Chapter 2.4 "Soluble Polymers").

Most important typical uses:

1.2 Insoluble polyvinylpyrrolidone (e.g. Kollidon CL)

Insoluble polyvinylpyrrolidone is obtained by popcorn polymerization of N-vinylpyrrolidone [2], which yields a crosslinked polymer [4-6]. The process is illustrated in Fig. 3 and uses either an alkali hydroxide at temperatures over 100 °C, which yields some bifunctional monomer, or a small percentage of bifunctional monomer in water to initiate crosslinking of the polymer.

Fig. 3. Production processes for insoluble N-vinylpyrrolidone popcorn polymers.

A comparison of the infrared spectra of the insoluble popcorn polymer obtained as shown in Fig. 3 and that of soluble polyvinylpyrrolidone shows practically no difference, while the infrared spectrum of chemically crosslinked insoluble polyvinylpyrrolidone polymer prepared in the laboratory is quite different, which indicates that the crosslinking in the popcorn polymer is essentially of a physical nature.

Insoluble polyvinylpyrrolidone finds extensive applications in the pharmaceutical and beverage industries as a swelling popcorn polymer with selective adsorptive properties. Its disintegration effect in tablets, its ability to hydrophylize insoluble active ingredients and to adsorb and form complexes are the main properties that make it useful as a pharmaceutical auxiliary. Today, Kollidon CL is regarded as one of the "superdisintegrants" for tablets.

Further, micronized insoluble polyvinylpyrrolidone is of considerable significance as an active substance against diarrhoea in certain parts of the world.

3.4 Applications of the insoluble Kollidon grades and Crospovidone M

3.4.1 General application properties

The insoluble grades of Kollidon and Crospovidone M possess a series of properties that are used in the manufacture of different pharmaceutical products:

Table 10: Applications and properties of Kollidon CL, Kollidon CL-M and Crospovidone M in pharmaceuticals

Acceleration of **tablet disintegration** and therefore also of dissolution and bioavailability of the active substances as a result of predictable swelling (disintegration effect)

Improvement of dissolution and bioavailability of drugs by complex formation

Preventive adsorption of polyphenols by complex formation

Stabilization of suspensions by Kollidon CL-M as a hydrophilic polymer

Stabilization of vitamins

Absorption of endotoxins by complexation

Absorption of water

Tablet marking of acetaminophen

The most important property of Kollidon CL as an auxiliary is its *disintegration effect*, which can be used in tablets, granules and hard gelatin capsules.

Its ability to form **complexes** is useful in solid and liquid dosage forms.

The improvement brought about by Kollidon CL and Kollidon CL-M in the dissolution of drugs is particularly useful for tablets and granules.

The use of Crospovidone M as an active substance against diarrhoea depends on its ability to form complexes, as does the use of crospovidone ("PVP") in removing polyphenols from wine, beer and plant extracts. The ability of Kollidon CL-M to *stabilize suspensions* finds its most important application in antibiotics, antacids and vitamin preparations.

The hygroscopicity of Kollidon CL and Kollidon CL-M (see Section 3.2.3.2) can be used to **absorb water** in preparations that contain moisture-sensitive drugs, to improve their stability. It almost certainly also contributes to the efficacy of Crospovidone M as an active substance in the treatment of diarrhoea.

17/01

2.4 Applications of the soluble Kollidon grades

2.4.1 General properties

The soluble grades of Kollidon possess a number of very useful properties for which they are widely used in pharmaceuticals.

Because of these properties, the products can perform different functions in different dosage forms.

Table 1: General properties of the soluble Kollidon grades in pharmaceuticals

Solubility in all conventional solvents.
Adhesive and binding power.
Film formation.
Affinity to hydrophilic and hydrophobic surfaces.
Ability to form complexes.
Availability in different average molecular weights.
Thickening properties.

Their excellent *solubility* in water and in other solvents used in pharmaceutical production (Section 2.2.2) is an advantage in almost all dosage forms, e.g. in wet granulation in tablet production, in oral solutions, syrups and drops, in injectables and topical solutions and in film coatings on tablets.

Their *adhesive and binding power* is particularly important in tableting (wet granulation, dry granulation, direct compression). This property is also useful in film coatings and adhesive gels.

Their *film-forming properties* are used in the film coating of tablets, in transdermal systems and in medicinal sprays.

Their *affinity to hydrophilic and hydrophobic surfaces* is particularly useful in the hydrophilization of a wide range of substances, ranging from hydrophobic tablet cores to permit sugar or film coating, to medical plastics.

Their *ability to form complexes* with such a large number of substances is a special feature of the Kollidon grades (Section 2.2.7). The complexes formed are almost always soluble and are stable only in an acid medium. This property can be used to increase the solubility of drugs in liquid dosage forms, as in the case of PVP iodine. In solid dosage forms, the ability to form complexes is used to increase bioavailability. A reduction in the local toxicity of certain drugs can also be achieved by complexation with Kollidon.

A special use for the complexation properties of Kollidon lies in the stabilization of proteins and enzymes in diagnostics.

Their *thickening properties* (Section 2.2.3) are used in oral and topical liquid dosage forms, e.g. syrups and suspensions.

Table 1: Main applications of Kollidon in the pharmaceutical industry

addes	Function	Pharmaceutical form
ber of very useful properties sals.	Fillers	Tablets, capsules, granules

if Kollidon lies in the stable	They are available in grades of different average molecular weight (Section 2.2.7), as the above properties almost all depend on the molecular weight, to a greater or lesser extent.	
used in oral and topical liquid	With increasing molecular weight, the dissolution rate of the soluble Kollidon grades decreases, while the adhesive power, the viscosity and often also the ability to form complexes increase. The rate of elimination from the organism after parenteral administration decreases with increasing molecular weight.	
	The dependence of the properties on the molecular weight makes it possible to provide the optimum grade for each dosage form or formulation and to achieve the optimum effect.
